Now let's check out functions in action so you can visually see how they work within a program. Here is an example for a simple function to display the given string.

Example: 7.2.1

```
def hello():
        print ("hello - Python")
        return
```

7.2.2 Advantages of User-defined Functions

1. Functions help us to divide a program into modules. This makes the code easier to manage.
2. It implements code reuse. Every time you need to execute a sequence of statements, all you need to do is to call the function.
3. Functions, allows us to change functionality easily, and different programmers can work on different functions.

7.3 Calling a Function

To call the hello() function from *example 7.2-1*, use the following code:

Example: 7.3.1

```
def hello():
        print ("hello - Python")
        return
(hello()
```

When you call the "hello()" function, the program displays the following string as output:

Output

hello – Python

Alternatively we can call the "hello()" function within the print() function as in the example given below.

Example: 7.3.2

```
def hello():
        print ("hello - Python")
        return
print (hello())
```

If the return has no argument, **"None"** will be displayed as the last statement of the output.
