Note

You can check out the full list of Python standard modules and what they are for. These files are in the Lib directory inside the location where Python is installed.

Some more command for wrapping C++ code

```
if __name__=='__main__':
    main(sys.argv[1:])
```

__name__ (A Special variable) in Python

Since there is no main() function in Python, when the command to run a Python program is given to the interpreter, the code that is at level 0 indentation (top must line of the program) is to be executed. However, before doing that, interpreter will define a few special variables. **__name__ is one such special variable which by default stores the name of the Python file.** If the source file is executed as the main program, the interpreter sets the __name__ variable to have a value "__main__".

__name__ is a built-in variable which evaluates to the name of the current module. Thus it can be used to check whether the current script is being run on its own.

For example consider the following

```
if __name__ == '__main__':
    main (sys.argv[1:])
```

If the command line Python program itself is going to execute first, then __name__ contains the string " __main__". The condition if " __main__"==" __main__": is true then the main function is called.

Note

sys.argv[1:] - get everything after the script name(file name).
sys.argv[0] is the script name (python program)
Remember "string slicing" you have studied in chapter 8.

14.7 Python program Executing C++ Program using control statement

Now let us write a Python program to read a C++ coding and execute its result. The steps for executing the C++ program to check a given number is palindrome or not is given below
