Example : 7.7.1

```
# return statment
def usr_abs (n):
        if n>=0:
                return n
        else:
                return –n
# Now invoking the function
x=int (input("Enter a number :")
print (usr_abs (x))
```

Output 1:

```
Enter a number : 25
        25
```

Output 2:

```
Enter a number : -25
        25
```

7.8 Scope of Variables

Scope of variable refers to the part of the program, where it is accessible, i.e., area where you can refer (use) it. We can say that scope holds the current set of variables and their values. We will study two types of scopes - **local scope** and **global scope**.

7.8.1 Local Scope

A variable declared inside the function's body is known as local variable.

Rules of local variable

- A variable with local scope can be accessed only within the function that it is created in.
- When a variable is created inside the function the variable becomes local to it.
- A local variable only exists while the function is executing.
- The formal parameters are also local to function.
