Where, statement in a class definition may be a variable declaration, decision control, loop or even a function definition. Variables defined inside a class are called as "Class Variable" and functions are called as "Methods". Class variable and methods are together known as members of the class. The class members should be accessed through objects or instance of class. A class can be defined anywhere in a Python program.

Example: Program to define a class

```
class Sample:
        x, y = 10, 20          # class variables
```

In the above code, name of the class is Sample and it has two variables x and y having the initial value 10 and 20 respectively. To access the values defined inside the class, you need an object or instance of the class.

10.3 Creating Objects

Once a class is created, next you should create an object or instance of that class. The process of creating object is called as "Class Instantiation".

Syntax:

Object_name = class_name( )

Note that the class instantiation uses function notation ie. class_name with ()

10.4 Accessing Class Members

Any class member ie. class variable or method (function) can be accessed by using object with a dot (.) operator.

Syntax:

Object_name . class_member

Example : Program to define a class and access its member variables

```
class Sample:
        x, y = 10, 20          #class variables
S=Sample( )          # class instantiation
print("Value of x = ", S.x)
print("Value of y = ", S.y)
print("Value of x and y = ", S.x+S.y)
```

Output :

```
Value of x =  10
Value of y =  20
Value of x and y =  30
```
